(54) Title: SYSTEM AND METHOD FOR GENERATING PIXEL VALUES FOR PIXELS IN AN IMAGE USING STRICTLY DETERMINISTIC METHODOLOGIES FOR GENERATING SAMPLE POINTS		
(57) Abstract <p>A computer graphics system generates pixel values for pixels in an image of objects in a scene, using strictly-deterministic low-discrepancy sequences, illustratively Halton sequences, as sample points for evaluating integrals which are used to simulate a number of computer graphic techniques, including: (1) soft shadows generated for scenes illuminated by a light source having a finite extent, such as a disk, as opposed to a point light source; (2) simulation of depth of field; (3) motion blur; (4) jittering. The computer graphics system uses the low-discrepancy sequence: (1) in connection with soft shadows, to generate sample points over the extent of the light source illuminating the scene; (2) in connection with simulation of depth of field, to generate sample points over the area of the lens between the scene and the image; (3) in connection with motion blur, to generate sample points over a time interval over which motion blur is to be simulated for moving objects in the scene; and (4) in connection with jittering, to generate jittered sample points over an image or a plurality of contiguous pixels. Unlike the random numbers used in connection with the Monte Carlo technique, the low discrepancy sequences ensure that the sample points are evenly distributed over a respective region or time interval, thereby reducing error in the image which can result from clumping of such sample points which can occur in the Monte Carlo technique. In particular, the invention facilitates the generation of images of improved quality when using the same number of sample points at the same computational cost as in the Monte Carlo technique.</p>

System And Method For Generating Pixel Values For Pixels In
An Image Using Strictly Deterministic Methodologies For
Generating Sample Points

5 The invention relates generally to the field of computer graphics, and more particularly to systems and methods for generating pixel values for pixels in the image.

10 In computer graphics, a computer is used to generate digital data that represents the projection of surfaces of objects in, for example, a three-dimensional scene, illuminated by one or more light sources, onto a two-dimensional image plane, to simulate the recording of the scene by, for example, a camera. The camera may include a
15 lens for projecting the image of the scene onto the image plane, or it may comprise a pinhole camera in which case no lens is used. The two-dimensional image is in the form of an array of picture elements (which are variable termed "pixels" or "pels"), and the digital data generated for
20 each pixel represents the colour and luminance of the scene as projected onto the image plane at the point of the respective pixel in the image plane. The surfaces of the objects may have any of a number of characteristics, including shape, colour, specularity, texture, and so
25 forth, which are preferably rendered in the image as closely as possible, to provide a realistic-looking image.

 Generally, the contributions of the light reflected from the various points in the scene to the pixel value representing the colour and intensity of a particular pixel
30 are expressed in the form of the one or more integrals of relatively complicated functions. Since the integrals used in computer graphics generally will not have a closed-form solution, numerical methods must be used to evaluate them and thereby generate the pixel value. Typically, a

-2-

conventional "Monte Carlo" method has been used in computer graphics to numerically evaluate the integrals. Generally, in the Monte Carlo method, to evaluate an integral

$$\langle f \rangle = \int_0^1 f(x) dx \quad (1),$$

- 5 where $f(x)$ is a real function on the real numerical interval from zero to 1, inclusive, first a number "N" statistically-independent random numbers x_i , $i=1, \dots, N$, are generated over the interval. The random numbers x_i are used as sample points for which sample values $f(x_i)$ are
- 10 generated for the function $f(x)$, and an estimate \bar{f} for the integral is generated as

$$\langle f \rangle \approx \bar{f} = \frac{1}{N} \sum_{i=1}^N f(x_i) \quad (2).$$

- As the number of random numbers used in generating the sample points $f(x_i)$ increases, the value of the estimate \bar{f}
- 15 will converge toward the actual value of the integral $\langle f \rangle$. Generally, the distribution of estimate values that will be generated for various values of "N," that is, for various numbers of samples, of being normal distributed around the actual value with a standard deviation σ which can be
- 20 estimated by

$$\sigma = \sqrt{\frac{1}{N-1} (\bar{f}^2 - \bar{f}^2)} \quad (3),$$

if the values x_i used to generate the sample values

-3-

$f(x_i)$ are statistically independent, that is, if the values x_i are truly generated at random.

Generally, it has been believed that random methodologies like the Monte Carlo method are necessary to ensure that undesirable artifacts, such as Moiré patterns and aliasing and the like, which are not in the scene, will not be generated in the generated image. However, several problems arise from use of the Monte Carlo method in computer graphics. First, since the sample points x_i used in the Monte Carlo method are randomly distributed, they may not be generally evenly distributed across the interval, but instead may clump in various regions over the interval over which the integral is to be evaluated. Accordingly, depending on the set of random numbers which are generated, in the Monte Carlo method for significant portions of the interval there may be no sample points x_i for which sample values $f(x_i)$ are generated. In that case, the error can become quite large. In the context of generating a pixel value in computer graphics, the pixel value that is actually generated using the Monte Carlo method may not reflect some elements which might otherwise be reflected if the sample points x_i were guaranteed to be generally evenly distributed over the interval. This problem can be alleviated somewhat by dividing the interval into a plurality of sub-intervals, but it is generally difficult to determine *a priori* the number of sub-intervals into which the interval should be divided, and, in addition, in a multi-dimensional integration region (which would actually be used in computer graphics, instead of the one-dimensional interval described here) the partitioning of the region into sub-regions of equal size can be quite complicated.

In addition, since the method makes use of random

-4-

numbers, the error $|\bar{f} - \langle f \rangle|$ (where $|x|$ represents the

absolute value of the value "x") between the estimate value \bar{f}

and actual value $\langle f \rangle$ is probabilistic, and, since the error values for various values of "N" are normal distributed
5 around the actual value $\langle f \rangle$, only sixty-eight percent of

the estimate values \bar{f} that might be generated are guaranteed to lie within one standard deviation of the actual value $\langle f \rangle$.

Furthermore, as is clear from equation (3), the
10 standard deviation σ decreases with increasing numbers of samples N, proportional to the reciprocal of square root of

"N" (that is, $1/\sqrt{N}$). Thus, if it is desired to reduce

the statistical error by a factor of two, it will be necessary to increase the number of samples N by a factor
15 of four, which, in turn, increases the computational load that is required to generate the pixel values, for each of the numerous pixels in the image.

Additionally, since the Monte Carlo method requires random numbers, an efficient mechanism for
20 generating random numbers is needed. Generally, digital computers are provided with so-called "random number" generators, which are computer programs which can be processed to generate a set of numbers that are approximately random. Since the random number generators
25 use deterministic techniques, the numbers that are generated are not truly random. However, the property that subsequent random numbers from a random number generator are statistically independent should be maintained by

-5-

deterministic implementations of pseudo-random numbers on a computer.

The invention provides a new and improved computer graphics system and method for generating pixel values for pixels in the image using a strictly deterministic methodology for generating sample points for use in evaluating integrals defining aspects of the image.

In brief summary, the computer graphics system in accordance with the invention generates pixel values for pixels in an image of objects in a scene, using strictly-deterministic low-discrepancy sequences, illustratively Halton sequences, as sample points for evaluating integrals which are used to simulate a number of computer graphic techniques, including

- (1) soft shadows generated for scenes illuminated by a light source having a finite extent, such as a disk, as opposed to a point light source;
- (2) Simulation of depth of field;
- (3) motion blur; and
- (4) jittering.

The computer graphics system uses the low-discrepancy sequences:

- (1) in connection with soft shadows, to generate sample points over the finite area of the light source illuminating the scene;
- (2) in connection with simulation of depth of field, to generate sample points over the area of the lens between the scene and the image;
- (3) in connection with motion blur, to generate sample points over a time interval over which motion blur is to be simulated for moving objects in the scene; and
- (4) in connection with jittering, to generate jittered sample points over an image or a plurality of contiguous pixels.

-6-

Unlike the random numbers used in connection with the Monte Carlo technique, the low discrepancy sequences ensure that the sample points are evenly distributed over a respective region or time interval, thereby reducing error in the image which can result from clumping of such sample points which can occur in the Monte Carlo technique.

In particular, the invention facilitates the generation of images of improved quality when using the same number of sample points at the same computational cost as in the Monte Carlo technique.

Advantageous features of the present invention are recited in the appended claims. The above and further advantages of this invention may be better understood by referring to the following description taken in conjunction with the accompanying drawings, in which:

FIG. 1 depicts a computer graphics system constructed in accordance with the invention; and

FIGS. 2 through 5 are flow-charts useful in understanding the operations of the computer graphics system depicted in FIG. 1, in accordance with the invention.

The invention provides a computer graphic system and method for generating pixel values for pixels in an image of a scene, which makes use of a strictly-deterministic methodology for generating sample points for use in generating sample values for evaluating the integral or integrals whose function(s) represent the contributions of the light reflected from the various points in the scene to the respective pixel value, rather than the random or pseudo-random Monte Carlo methodology which has been used in the past. The strictly-deterministic methodology ensures a priori that the sample points will be generally

-7-

evenly distributed over the interval or region over which the integral(s) is (are) to be evaluated in a low-discrepancy manner.

FIG. 1 attached hereto depicts an illustrative computer system 10 that makes use of such a strictly deterministic methodology. With reference to FIG. 1, the computer system 10 in one embodiment includes a processor module 11 and operator interface elements comprising operator input components such as a keyboard 12A and/or a mouse 12B (generally identified as operator input element(s) 12) and an operator output element such as a video display device 13. The illustrative computer system 10 is of the conventional stored-program computer architecture. The processor module 11 includes, for example, one or more processors, memories and mass storage devices such as disk and/or tape storage elements (not separately shown) which perform processing and storage operations in connection with digital data provided thereto. The operator input element(s) 12 are provided to permit an operator to input information for processing. The video display device 13 is provided to display output information generated by the processor module 11 on a screen 14 to the operator, including data that the operator may input for processing, information that the operator may input to control processing, as well as information generated during processing. The processor module 11 generates information for display by the video display device 13 using a so-called "graphical user interface" ("GUI"), in which information for various applications programs is displayed using various "windows." Although the computer system 10 is shown as comprising particular components, such as the keyboard 12A and mouse 12B for receiving input information from an operator, and a video display device 13 for displaying output information to the

-8-

operator, it will be appreciated that the computer system 10 may include a variety of components in addition to or instead of those depicted in FIG. 1.

In addition, the processor module 11 includes one or more network ports, generally identified by reference numeral 14, which are connected to communication links which connect the computer system 10 in a computer network. The network ports enable the computer system 10 to transmit information to, and receive information from, other computer systems and other devices in the network. In a typical network organized according to, for example, the client-server paradigm, certain computer systems in the network are designated as servers, which store data and programs (generally, "information") for processing by the other, client computer systems, thereby to enable the client computer systems to conveniently share the information. A client computer system which needs access to information maintained by a particular server will enable the server to download the information to it over the network. After processing the data, the client computer system may also return the processed data to the server for storage. In addition to computer systems (including the above-described servers and clients), a network may also include, for example, printers and facsimile devices, digital audio or video storage and distribution devices, and the like, which may be shared among the various computer systems connected in the network. The communication links interconnecting the computer systems in the network may, as is conventional, comprise any convenient information-carrying medium, including wires, optical fibres or other media for carrying signals among the computer systems. Computer systems transfer information over the network by means of messages transferred over the communication links, with each message

-9-

including information and an identifier identifying the device to receive the message.

As noted above, the computer graphics system 10 generates pixel values for pixels in an image of a scene, which makes use of a strictly-deterministic methodology for selecting sample points used to generate sample values which are then used in evaluating the integral or integrals whose function(s) represent the contributions of the light reflected from the various points in the scene to the respective pixel value. In one particular embodiment, the strictly-deterministic methodology used by the computer graphics system 10 provides a low-discrepancy sample point sequence which ensures, a priori, that the sample points are generally evenly distributed throughout the region over which the respective integrals are being evaluated. In one embodiment, the sample points that are used are based on a so-called Halton sequence. See, for example, J. H. Halton, *Numerische Mathematik*, Vol. 2, pp. 84-90 (1960) and W. H. Press, et al., *Numerical Recipes in Fortran* (2d Edition) page 300 (Cambridge University Press, 1992). In a Halton sequence generated for number base "p," where base "p" is a selected prime number, the "k-th" value of the sequence, represented by H_p^k is generated by

(1) writing the value "k" as a numerical representation of the value in the selected base "p," thereby to provide a representation for the value as $D_M D_{M-1} \dots D_2 D_1$, where D_m ($m=1, 2, \dots, M$)

are the digits of the representation, and
(2) putting a radix point (corresponding to a decimal point for numbers written in base ten) at the end of the representation $D_M D_{M-1} \dots D_2 D_1$ written in step (1) above, and reflecting the digits around

-10-

the radix point to provide $0.D_1D_2\cdots D_{M-1}D_M$, which

corresponds to H_p^k .

It will be appreciated that, regardless of the base "p" selected for the representation, for any series of values, one, two, ... "k," written in base "p," the least significant digits of the representation will change at a faster rate than the most significant digits. As a result, in the Halton sequence $H_p^1, H_p^2, \dots H_p^k$, the most significant digits will change at the faster rate, so that the early values in the sequence will be generally widely distributed over the interval from zero to one, and later values in the sequence will fill in interstices among the earlier values in the sequence. Unlike the random or pseudo-random numbers used in the Monte Carlo method as described above, the values of the Halton sequence are not statistically independent; on the contrary, the values of the Halton sequence are strictly deterministic, "maximally avoiding" each other over the interval, and so they will not clump, whereas the random or pseudo-random numbers used in the Monte Carlo method may clump.

It will be appreciated that the Halton sequence as described above provides a sequence of values over the interval from zero to one, inclusive along a single dimension. A multi-dimensional Halton sequence can be generated in a similar manner, but using a different base for each dimension.

A generalized Halton sequence, of which the Halton sequence described above is a special case, is generated as follows. For each starting point along the numerical interval from zero to one, inclusive, a different Halton sequence is generated. Defining the pseudo-sum $x \oplus_p y$ for any x and y over the interval from zero to one, inclusive, for any integer "p" having a value greater than

-11-

two, the pseudo-sum is formed by adding the digits representing "x" and "y" in reverse order, from the most-significant digit to the least-significant digit, and for each addition also adding in the carry generated from the sum of next more significant digits. Thus, if "x" in base "p" is represented by $0.X_1X_2\cdots X_{M-1}X_M$, where each " X_n " is a digit in base "p," and if "y" in base "p" is represented by $0.Y_1Y_2\cdots Y_{N-1}Y_N$, where each " Y_n " is a digit in base "p" (and where "M," the number of digits in the representation of "x" in base "p",, and "N," the number of digits in the representation of "y" in base "p",, may differ), then the pseudo-sum "z" is represented by $0.Z_1Z_2\cdots Z_{L-1}Z_L$, where each " Z_1 " is a digit in base "p" given by $Z_1 = (X_1 + Y_1 + C_1) \bmod p$, where "mod" represents the modulo function, and

$$C_1 = \begin{cases} 1 & \text{for } X_{1-1} + Y_{1-1} + C_{1-1} \geq p \\ 0 & \text{otherwise} \end{cases} \quad \text{and } C_1 \text{ is set to zero.}$$

Using the pseudo-sum function as described above, the generalized Halton sequence is generated as follows. If "p" is an integer, and x_0 is an arbitrary value on the interval from zero to one, inclusive, then the "p"-adic von Neumann-Kakutani transformation $T_p(x)$ is given by

$$T_p(x) := x \oplus_p \frac{1}{p} \quad (4),$$

and the generalized Halton sequence x_0, x_1, x_2, \dots is defined recursively as

$$x_{n+1} = T_p(x_n) \quad (5).$$

-12-

From equations (4) and (5), it is clear that, for any value for "p," the generalized Halton sequence can provide a different sequence will be generated for each starting value of "x," that is, for each x_0 . It will be appreciated
5 that the Halton sequence H_p^k as described above is a special case of the generalized Halton sequence (equations (4) and (5)) for $x_0=0$.

The use of the low-discrepancy sequence in evaluating integrals to generate pixel values for pixels in
10 an image in computer graphics will be illustrated in connection several specific computer applications, in particular, the generation of pixel values for images representing

(1) soft shadows generated for scenes illuminated
15 by a light source having a finite extent, such as a disk, as opposed to a point light source;

(2) Simulation of depth of field;

(3) motion blur; and

(4) jittering.

20 Operations performed by the computer graphics system
10 in connection with each of these will be described below.

-13-

(1) Soft Shadows

Soft shadows can occur in a scene when objects in the scene are illuminated by a light source having an identifiable area, such as a disk, instead of a point light source. Illustratively, when a solar eclipse occurs, the penumbra portion of the shadow cast by the moon on the earth is a soft shadow, and the umbra portion constitutes a full shadow. The umbra portion of the eclipse occurs in regions of the earth for which the moon completely obscures the sun, and the penumbra portion occurs in regions for which the moon partially obscures the sun. The degree of shadow in the penumbra lessens as one proceeds outwardly from the umbra, and the penumbra constitutes the "soft shadow" for the eclipse. For a particular shadow in a scene, the soft shadow represents a grading from the region (if any) of the scene that is in full shadow to the region for which there is no shadow.

In a scene, a portion of a pixel value for a point in a scene representing illumination by a light source having an area is generated by averaging the illumination of a particular point in a scene by a light source over the area of the light source. If the point in the scene is in a full shadow region, which may occur if the point is completely obscured by one or more objects in the scene, then the average will represent a luminance level representative of full shadow. Similarly, if the point is in a no-shadow region, then the average will represent a luminance level representative of no shadow. On the other hand, if the point is partially obscured from the full area of the light source by objects in the scene, and thus is in a soft shadow region, then the average will represent an intermediate luminance level based on the amount of the light source that is obscured. In any case, the average is given illustratively by the two-dimensional

-14-

integral

$$I(\vec{x}) = \int_{A'} \frac{V(\vec{x}, \vec{x}')}{|\vec{x} - \vec{x}'|^2} L_e(\vec{x}') dA' \quad (6),$$

where (\vec{x}) is a point in the scene for which the illumination value is being generated, (\vec{x}') is a point on the area light source, $I(\vec{x})$ represents the illumination at the point (\vec{x}) in the scene, $L_e(\vec{x})$ denotes the level of light emission of the area light source, and $V(\vec{x}, \vec{x}')$ is a visibility function that equals one if the point (\vec{x}') on the light source is visible from the point (\vec{x}) in the scene and zero if the point (\vec{x}') on the light source is not visible from the point (\vec{x}) in the scene. The integral is evaluated over the area A' of the light source. The formulation of the function $\frac{V(\vec{x}, \vec{x}')}{|\vec{x} - \vec{x}'|^2} L_e(\vec{x}')$

-15-

for a particular image is known to one of skill in the art.

In accordance with the invention, the computer graphics system 10 evaluates the integral (equation (6)) to generate a pixel value by selecting a number "N" of sample

5 points (\vec{x}_i') using a two-dimensional generalized Halton

sequence. After the sample points (\vec{x}_i') are generated,

the computer graphics system 10 evaluates the function

$$\frac{V(\vec{x}, \vec{x}_i')}{|\vec{x} - \vec{x}_i'|^2} L_o(\vec{x}_i') \quad (7)$$

for each of the generated sample points and approximates
10 the value of the integral (equation (6)) as

$$I(\vec{x}) \approx \overline{I(\vec{x})} = \frac{1}{N} \sum_{i=1}^N \frac{V(\vec{x}, \vec{x}_i')}{|\vec{x} - \vec{x}_i'|^2} L_o(\vec{x}_i') \quad (8)$$

for each of the points (\vec{x}) in the scene for which the

illumination value $I(\vec{x})$ is to be generated. The use of

a low-discrepancy sequence, illustratively the Halton
15 sequence, will ensure that the sample points will not
clump, but instead will be evenly distributed over the area
of the light source.

-16-

In one embodiment, for each of the points (\vec{x})

in the scene for which the illumination value $I(\vec{x})$ is to

be generated, the computer graphics system 10 uses a different Halton sequence, generated in accordance with the

5 generalized Halton sequence methodology described above (equation (5)), so as to avoid generating pixel values for which the soft shadows might otherwise appear blocky. In that embodiment, the particular Halton sequence is generated using a base value x_0 which is based on the
10 coordinates of the point in the image for which the pixel value is being generated that is associated with the point (\vec{x})

in the scene.

Operations described above in connection with the generation of pixel values so as to provide soft shadows
15 are depicted on the flow-chart in FIG. 2. Since the operations as depicted in that flow-chart will be readily apparent to those skilled in the art from the above description, the flow-chart in that FIG. will not be separately described in this specification.

20 It will be appreciated that the function

$$\frac{V(\vec{x}, \vec{x}')}{|\vec{x} - \vec{x}'|^2} L_o(\vec{x}') \text{ used in equation (6) is illustrative of}$$

the functions that can be used in connection with generation of pixel values to simulate soft shadows, and other functions will be apparent to those skilled in the
25 art, with corresponding changes in equations (7) and (8).

-17-

For example, although in the denominator of $\frac{V(\vec{x}, \vec{x}')}{|\vec{x} - \vec{x}'|^2}$ in

equation (6), the term " $|\vec{x} - \vec{x}'|$ " is indicated as being

taken to the second power (that is, squared), it will be appreciated that other powers can be used, in which case
 5 equations (7) and (8) would be modified accordingly. In addition, although the Halton sequence has been indicated as being used to provide the sample points for the evaluation, it will be appreciated that other low-discrepancy sequences, which are known in the art, could be
 10 used instead.

In addition, it will be appreciated that, although the computer graphics system 10 has been described as simulating soft shadows in connection with area light sources, the computer graphics system 10 can also simulate
 15 soft shadows in connection with a linear light source in a manner similar to that described above. As with simulation of soft shadows for an area light source, the computer graphics system 10 will constrain the sample points (\vec{x}_i')

to fall on the light source. In addition, if the light
 20 source is a linear light source, the computer graphics system 10 can generate the sample points (\vec{x}_i') using a

one-dimensional generalized Halton sequence.

(2) Depth of Field Simulation

As noted above, the computer graphics system 10

-18-

can generate pixel values defining a rendered image representing an image which would be recorded for a pinhole camera, or alternatively it can generate pixel values defining a rendered image representing an image which would be recorded for a camera with a lens. Typically, for a camera without a lens, all of the objects are normally in focus. However, for a conventional camera with a lens, the objects at a particular distance from the lens, as well as objects within a plane of predetermined distance thereof, known as the "depth of field" would be in focus. For objects which are closer or more distant, the objects would be increasingly blurred.

To simulate generation of an image for a camera with a depth of field, the computer graphics system generates a pixel value for each pixel based on the evaluation of the integral

$$L(x, y) = \int_{A_{eff}} \bar{L}(x, y, x', y') dx' dy' \quad (9),$$

where $\bar{L}(x, y, x', y')$ denotes the luminance coming from the point (x', y') on the lens in the direction of the point (x, y) in the image plane. The computer graphics system evaluates the integral over the area A_{eff} of the lens. The formulation of the function $\bar{L}(x, y, x', y')$ for a particular image is known to one of skill in the art.

In accordance with the invention, the computer graphics system evaluates the integral (equation (9)) to generate a pixel value by selecting a number "N" of sample points for points (x_i, y_i) on the lens using the Halton sequence to provide the sample points. After the sample points are generated, the computer graphics system

-19-

evaluates the function $\bar{L}(x, y, x', y')$ for each of the "N" sample points (x_i, y_i) and approximates the integral (equation (9)) as

$$L(x, y) = \frac{1}{N} \sum_{i=1}^N \bar{L}(x, y, x_i, y_i) \quad (10),$$

5 In one particular embodiment, for each point (x_i, y_i) on the image plane, the computer graphics system 10 uses a different Halton sequence, generated in accordance with the generalized Halton sequence methodology described above (equation (5)), so as to avoid generating pixel values for
10 which the rendered image might otherwise appear blocky. In that embodiment, the particular Halton sequence is generated using a base value x_0 which is based on the coordinates of the point in the image for which the pixel value is being generated that is associated with the point
15 (x_i, y_i) in the image plane. The use of a low-discrepancy sequence, illustratively the Halton sequence, will ensure that the sample points will not clump, but instead will be evenly distributed over the area of the lens.

Operations described above in connection with the
20 generation of pixel values so as to provide depth of field are depicted on the flow-chart in FIG. 3. Since the operations as depicted in that flow-chart will be readily apparent to those skilled in the art from the above description, the flow-chart in that FIG. will not be
25 separately described in this specification.

The use of sample points (x_i) selected as described above for the evaluation of the integral (equation (9)) is advantageous in that the use of the low-discrepancy set of sample points has a "self-avoiding"

-20-

property that ensures that the sample points will not be clumped together, which clumping is possible with prior methodologies such as the random-number-based Monte Carlo method. A further advantage is that the number of sample
5 points (x_i) does not need to be selected a priori prior to the computation.

It will be appreciated that the function $\bar{L}(x, y, x', y')$ used in equation (9) is illustrative of the functions that can be used in connection with generation of
10 pixel values to simulate depth of field, and other functions will be apparent to those skilled in the art, with corresponding changes in equation (10). In addition, although the Halton sequence has been indicated as being used to provide the sample points for the evaluation, it
15 will be appreciated that other low-discrepancy sequences, which are known in the art, could be used instead.

(3) Motion Blur

Motion blur occurs when, for example, an object in a scene being recorded by a stationary camera is moving.
20 The motion blur occurs because the camera's shutter has a non-zero time interval over which it is open, and, if the camera is not moved to so as to maintain the moving object at precisely the same point in the image, the point at which the moving object appears in the image moves over the
25 time interval. Accordingly, edges of the object which are transverse to the direction of motion appears to be blurred over the image.

To simulate generation of an image of a scene in which an object is moving, by a camera whose shutter has a
30 non-zero time interval over which it is open, the computer graphics system 10 generates a pixel value for each pixel based on the evaluation of the integral

-21-

$$L(x,y) = \frac{1}{t_s} \int_0^{t_s} L(x,y,t) dt \quad (11)$$

where $L(x,y)$ is the luminance of point (x,y) , $L(x,y,t)$ is the luminance of point (x,y) in the image at time " t ," and " t_s " is the time period over which the shutter is open. It will be appreciated that $L(x,y)$ is essentially the average of $L(x,y,t)$ over time t_s . The formulation of the function $L(x,y,t)$ for a particular image is known to one of skill in the art.

10 In accordance with the invention, the computer graphics system 10 evaluates the integral (equation (11)) to generate a pixel value by selecting a number " N " of sample points for points (t_i) over the time interval from zero to t_s using the Halton sequence to provide the sample points. After the sample points are generated, the computer graphics system 10 evaluates the function $L(x,y,t)$ for each of the " N " sample points (t_i) and approximates the integral (equation (11)) as

$$L(x,y) \approx \overline{L(x,y)} = \frac{1}{N} \sum_{i=1}^N L(x,y,t_i) \quad (12)$$

20 In one particular embodiment, for each pixel in the image, the computer graphics system 10 uses a different generalized Halton sequence, generated in accordance with the generalized Halton sequence methodology described above (equation (5)), so as to avoid generating pixel values for which the rendered image might otherwise appear blocky. In that embodiment, the particular Halton sequence is generated using a base value x_0 which is based on the

-22-

coordinates of the point (x,y) in the image for which the pixel value is being generated. The use of a low-discrepancy sequence, illustratively the Halton sequence, will ensure that the sample points will not clump, but
5 instead will be evenly distributed over the time period over which the integral (equation (11)) is to be evaluated).

Operations described above in connection with the generation of pixel values so as to provide motion blur are depicted on the flow-chart in FIG. 4. Since the operations
10 as depicted in that flow-chart will be readily apparent to those skilled in the art from the above description, the flow-chart in that FIG. will not be separately described in this specification.

It will be appreciated that the function
15 $L(x,y,t)$ used in equation (11) is illustrative of the functions that can be used in connection with generation of pixel values to simulate depth of field, and other functions will be apparent to those skilled in the art, with corresponding changes in equation (12). In addition,
20 although the Halton sequence has been indicated as being used to provide the sample points for the evaluation, it will be appreciated that other low-discrepancy sequences, which are known in the art, could be used instead.

In addition, it will be appreciated that the
25 computer graphics system 10 may use a one-dimensional Halton sequence to generate sample points (t_i) for use in equation (12) along a temporal dimension "t" for each sample point (x,y) in the image. In that case, during generation of the pixel value, the computer graphics system
30 10 will generate the luminance value $L(x,y)$ for the sample point (x,y) in accordance with equation (12). Alternatively, the computer graphics system 10 may use, for example, a three-dimensional Halton sequence to generate sample points (x_i, y_i, t_i) along both the temporal dimension

-23-

"t" and spatial dimensions "x" and "y" of the image plane, for use in equation (12), and can generate the luminance value for the pixel using equation (12) using the luminance values $L(x_i, y_i, t_i)$, where (x_i, y_i) are sample points within the region of the pixel.

(4) Jittering

To generate a pixel value for a pixel which represents the colour of the pixel at the respective point in the image, the colour represented by the pixel value is averaged over the area of the pixel. To simulate that, the computer graphics system 10 generates the pixel value for pixel P_i to have an averaged colour L_i by evaluating the integral

$$L_i = \frac{1}{|P_i|} \int_{P_i} L(x, y) dx dy \quad (13),$$

where $L(x, y)$ represents the colour at point (x, y) in the image, and $|P_i|$ represents the area of the pixel P_i . The formulation of the function $L(x, y)$ for a particular image is known to one of skill in the art.

The computer graphics system 10 can evaluate the integral (equation (13)) to generate a pixel value by selecting a number "N" of sample points (x_i, y_i) in the pixel P_i using the Halton sequence to provide the sample points. After the sample points are generated, the computer graphics system 10 evaluates the function $L(x, y)$ for each of the "N" sample points (x_i, y_i) and approximates the integral (equation (13)) as

$$L(x, y) \approx \overline{L(x, y)} = \frac{1}{N} \sum_{i=1}^N L(x_i, y_i) \quad (14)$$

-24-

Several problems arise, however, if the integral (equation (13)) is evaluated using a Halton sequence generated for each pixel. First, although the Halton sequence guarantees that no clumping occurs within a single pixel, it will not guarantee that clumping will not occur at boundaries of adjacent pixels. In addition, the Halton sequences generated for the pixels would exhibit periodicity on the pixel level, in which case artifacts may be generated in the image which can be evident to the eye.

Thus, to accommodate these problems, in accordance with the invention, the computer graphics system 10 generates the Halton sequence to generate the sample points either for the image as a whole or for a predetermined number of contiguous pixels in the following manner. Initially, the computer graphics system 10 divides the image or the predetermined number of contiguous pixels based on a grid of size "n" by "m," where $n=2^i$ is a positive power ("i") of two and $m=3^j$ is a positive power ("j") of three. (In this description, two and three are the number bases (that is, "p" in equations 4 and 5 describing the one-dimensional Halton sequence) selected for generation of the two-dimensional Halton sequence; if the computer graphics system 10 uses other number bases for generation of the two-dimensional Halton sequence, then "n" and "m" would be selected to be powers of those number bases.) Then the computer graphics system 10 generates the set of sample points (x_i, y_i) to be used in evaluating equation (14) as (nH_2^k, mH_3^k) for $k=1, \dots, nm$, which constitutes a scaled two-dimensional Halton sequence, with the scaling being in accordance with the values of "n" and "m". The sample points so generated, precisely one sample point will be provided in each of a plurality of sub-pixels in each pixel, if the left and lower boundaries of each sub-pixel are deemed to form part of the sub-pixel and the right and

-25-

upper boundaries of each sub-pixel are deemed not to form part of the sub-pixel.

For example, if the computer graphics system 10 is to generate sample points on "N" by "N" sub-pixels for each pixel, and if the number of columns in the image or the selected sub-set of contiguous pixels is Res_x , and if the number of rows of pixels in the image or the selected sub-set of contiguous pixels is Res_y , then the computer graphics system 10 can generate a number of $N \cdot Res_x \times N \cdot Res_y$ of sample points to be used with the pixels in the image or selected subset of pixels by initially selecting integers "i" and "j" such that $n=2^i \geq N \cdot Res_x$ and $m=3^j \geq N \cdot Res_y$. Note that the sub-pixel grid of "n" by "m" sub-pixels will in general be larger than the size of the image or selected subset of contiguous pixels.

According to the mechanism described above, the computer graphics system 10 can evaluate the integral in equation (14) for each pixel using the sample points which are provided within the area of the respective pixel.

Several benefits arise from generating sample points using the scaled two-dimensional Halton sequence (nH_2^k, mH_3^k) for the entire image or selected sub-set of contiguous pixels in evaluating the integral in equation (14), instead of using the unscaled Halton sequence (that is, illustratively, (H_2^k, H_3^k)) within one pixel as the sample points. First, by using a scaled two-dimensional Halton sequence, periodicity of the sample points on the level of a pixel, which can occur in connection with the unscaled two-dimensional Halton sequence, will be avoided. In addition, the use of a scaled two-dimensional Halton sequence (nH_2^k, mH_3^k) will ensure that no clumping of sample points will occur at the boundaries of adjacent pixels, which can occur in connection with the unscaled two-dimensional Halton sequence. Therefore, the use of a

-26-

scaled two-dimensional Halton sequence (nH_k , mH_k) will ensure that the sample points will be evenly distributed throughout the entire image or contiguous region of pixels. This will also be the case if relatively few sample points
5 are used, and even if only one sample point per pixel is used.

Operations described above in connection with the generation of pixel values so as to provide jittering are depicted on the flow-chart in FIG. 5. Since the operations
10 as depicted in that flow-chart will be readily apparent to those skilled in the art from the above description, the flow-chart in that FIG. will not be separately described in this specification.

It will be appreciated that the function $L(x,y)$
15 used in equation (13) is illustrative of the functions that can be used in connection with generation of pixel values to simulate jittering, and other functions will be apparent to those skilled in the art, with corresponding changes in equation (14). In addition, although the Halton sequence
20 has been indicated as being used to provide the sample points for the evaluation, it will be appreciated that other low-discrepancy sequences, which are known in the art, could be used instead.

It will be appreciated that a system in
25 accordance with the invention can be constructed in whole or in part from special purpose hardware or a general purpose computer system, or any combination thereof, any portion of which may be controlled by a suitable program. Any program may in whole or in part comprise part of or be
30 stored on the system in a conventional manner, or it may in whole or in part be provided in to the system over a network or other mechanism for transferring information in a conventional manner. In addition, it will be appreciated that the system may be operated and/or otherwise controlled

-27-

by means of information provided by an operator using operator input elements (not shown) which may be connected directly to the system or which may transfer the information to the system over a network or other mechanism
5 for transferring information in a conventional manner.

The foregoing description has been limited to a specific embodiment of this invention. It will be apparent, however, that various variations and modifications may be made to the invention, with the
10 attainment of some or all of the advantages of the invention. The appended claims cover these and such other variations and modifications as come within the true spirit and scope of the invention.

Generally the invention provides a computer
15 graphics system generates pixel values for pixels in an image of objects in a scene, using strictly-deterministic low-discrepancy sequences, illustratively Halton sequences, as sample points for evaluating integrals which are used to simulate a number of computer graphic techniques,
20 including:

(1) soft shadows generated for scenes illuminated by a light source having a finite extent, such as a disk, as opposed to a point light source;

- (2) Simulation of depth of field;
25 (3) motion blur;
(4) jittering.

The computer graphics system uses the low-discrepancy sequence:

(1) in connection with soft shadows, to
30 generate sample points over the extent of the light source illuminating the scene;

(2) in connection with simulation of depth of field, to generate sample points over the area of the lens between the scene and the image;

-28-

(3) in connection with motion blur, to generate sample points over a time interval over which motion blur is to be simulated for moving objects in the scene; and

(4) in connection with jittering, to generate
5 jittered sample points over an image or a plurality of contiguous pixels.

Unlike the random numbers used in connection with the Monte Carlo technique, the low discrepancy sequences ensure that the sample points are evenly distributed over a
10 respective region or time interval, thereby reducing error in the image which can result from clumping of such sample points which can occur in the Monte Carlo technique.

In particular, the invention facilitates the generation of images of improved quality when using the
15 same number of sample points at the same computational cost as in the Monte Carlo technique.

-29-

Claims:

1. A computer graphics system for generating a pixel value for a pixel in an image, the pixel being representative of a point in a scene, the computer graphics system generating the pixel value to provide a soft shadow that is represented by an evaluation of an integral of a selected function over a finite extent of a light source, the computer graphics system comprising:

A. a sample point generator for generating a set of sample points representing points on the finite extent of the light source, the sample point generator using a predetermined strictly-deterministic low-discrepancy sequence to generate the sample points;

B. a function evaluator for generating a plurality of function values each representing an evaluation of said selected function at one of the sample points generated by said sample point generator;

C. an illumination value generator for generating an illumination level value for the point in the scene as the average of said function values generated by said function evaluator; and

D. a pixel value generator for using the illumination level value generated for the point in the scene in generating the pixel value.

2. A computer graphics system as defined in claim 1, in which said predetermined low-discrepancy sequence is a generalized Halton sequence.

3. A computer graphics system as defined in claim 1 or claim 2 in which the selected function is

-30-

$$\frac{V(\vec{x}, \vec{x}')}{|\vec{x} - \vec{x}'|^2} L_s(\vec{x}'), \text{ where } (\vec{x}) \text{ is the point in the scene, } (\vec{x}')$$

is a point on the area light source, $L_s(\vec{x})$ denotes a level of light emission of the area light source, and $V(\vec{x}, \vec{x}')$ is a visibility function that equals one if the point (\vec{x}') on the light source is visible from the point (\vec{x}) in the scene and zero if the if the point (\vec{x}') on the light source is not visible from the point (\vec{x}) in the scene.

4. A computer graphics method for generating a pixel value for a pixel in an image, the pixel being representative of a point in a scene, the computer graphics method generating the pixel value to provide a soft shadow that is represented by an evaluation of an integral of a selected function over a finite extent of a light source, the computer graphics method comprising the steps of:

- A. generating a set of sample points representing points on the finite extent of the light source using a predetermined strictly-deterministic low-discrepancy sequence;
- B. generating a plurality of function values each representing an evaluation of said selected function at one of the sample points;
- C. generating an illumination level value for the point in the scene as the

-31-

average of said function values; and

D. using the illumination level value generated for the point in the scene in generating the pixel value.

5. A computer graphics method as defined in claim 4 in which said predetermined low-discrepancy sequence is a generalized Halton sequence.

6. A computer graphics method as defined in claim 4 or claim 5 in which the selected

function is $\frac{V(\vec{x}, \vec{x}')}{|\vec{x} - \vec{x}'|^2} L_s(\vec{x}')$, where (\vec{x}) is the point in the scene, (\vec{x}') is a

point on the area light source, $L_s(\vec{x})$ denotes a level of light emission of the area

light source, and $V(\vec{x}, \vec{x}')$ is a visibility function that equals one if the point

(\vec{x}') on the light source is visible from the point (\vec{x}) in the scene and zero if the

if the point (\vec{x}') on the light source is not visible from the point (\vec{x}) in the scene.

7. A computer graphics system for generating a pixel value for a pixel in an image, the pixel being representative of a point in a scene, the computer graphics system generating the pixel value to provide a depth of field that is represented by an evaluation of an integral of a selected function over an area of a lens, the computer

-32-

graphics system comprising:

- A. a sample point generator for generating a set of sample points representing points on the area of the lens, the sample point generator using a predetermined strictly-deterministic low-discrepancy sequence to generate the sample points;
- B. a function evaluator for generating a plurality of function values each representing an evaluation of said selected function at one of the sample points generated by said sample point generator;
- C. a luminance value generator for generating a luminance value for the pixel as the average of said function values generated by said function evaluator; and
- D. a pixel value generator for using the luminance value generated for the point in the scene in generating the pixel value.

8. A computer graphics system as defined in claim 7 in which said predetermined low-discrepancy sequence is a generalized Halton sequence.

9. A computer graphics system as defined in claim 7 or claim 8 in which the selected function is $\bar{L}(x,y,x',y')$, denoting the luminance coming from the point (x',y') on the lens towards point (x,y) in the image plane.

10. A computer graphics method for generating a pixel value for a pixel in an image, the pixel being representative of a point in a scene, the computer graphics method generating the pixel value to provide a depth of field that is represented by an evaluation of an integral of a selected function over an area of a lens, the computer graphics method comprising the steps of:

- A. generating a set of sample points representing points on the area of the lens using a predetermined strictly-deterministic low-discrepancy sequence.

-33-

- B. generating a plurality of function values each representing an evaluation of said selected function at one of the sample points;
- C. generating a luminance value for the pixel as the average of said function values; and
- D. using the luminance value generated for the point in the scene in generating the pixel value.

11. A computer graphics method as defined in claim 10 in which said predetermined low-discrepancy sequence is a generalized Halton sequence.

12. A computer graphics method as defined in claim 10 or claim 11 in which the selected function is $\bar{L}(x,y,x',y')$, denoting the luminance coming from the point (x',y') on the lens towards point (x,y) in the image plane.

13. A computer graphics system for generating a pixel value for a pixel in an image, the pixel being representative of a point in a scene, the computer graphics system generating the pixel value to provide a motion-blur that is represented by an evaluation of an integral of a selected function over a selected time interval, the computer graphics system comprising:

- A. a sample point generator for generating a set of sample points representing points on the time interval, the sample point generator using a predetermined low-discrepancy strictly-deterministic sequence to generate the sample points;
- B. a function evaluator for generating a plurality of function values each representing an evaluation of said selected function at one of the sample points generated by said sample point generator;
- C. a luminance value generator for generating a luminance level value for the pixel as the average of said function values generated by said function

-34-

evaluator; and

D. a pixel value generator for using the luminance value generated for the point in the scene in generating the pixel value.

14. A computer graphics system as defined in claim 13 in which said predetermined low-discrepancy sequence is a generalized Halton sequence.

15. A computer graphics system as defined in claim 13 or claim 14 in which the selected function is $L(x,y,t)$ representing the luminance of point (x,y) in the image at time "t."

16. A computer graphics method for generating a pixel value for a pixel in an image, the pixel being representative of a point in a scene, the pixel value generated so as to provide a motion blur that is represented by an evaluation of an integral of a selected function over a selected time interval, the computer graphics method comprising the steps of:

A. generating a set of sample points representing points on the time interval, the sample point-generator using a predetermined strictly-deterministic low-discrepancy sequence;

B. generating a plurality of function values each representing an evaluation of said selected function at one of the sample points;

C. generating a luminance level value for the pixel as the average of said function values; and

D. using the luminance value generated for the point in the scene in generating the pixel value.

17. A computer graphics method as defined in claim 16 in which said predetermined low-discrepancy sequence is a generalized Halton sequence.

-35-

18. A computer graphics method as defined in claim 16 or claim 17 in which the selected function is $L(x,y,t)$ representing the luminance of point (x,y) in the image at time "t."

19. A computer graphics system for generating a pixel value for a pixel in an image, the pixel being representative of a point in a scene, the computer graphics system generating the pixel value to provide a jittering that is represented by an evaluation of an integral of a selected function over an area in the image for the pixel, the computer graphics system comprising:

A. a sample point generator for generating a set of sample points representing points in a plurality of contiguous pixels in the image, the plurality of contiguous pixels including the pixel for which the pixel value is to be generated, the sample point generator using a predetermined strictly-deterministic low-discrepancy sequence to generate the sample points;

B. a function evaluator for generating a plurality of function values each representing an evaluation of said selected function at one of the sample points generated by said sample point generator;

C. a pixel value generator for generating the pixel value for the pixel as the average of said function values generated by said function evaluator.

20. A computer graphics system as defined in claim 19 in which said predetermined low-discrepancy sequence is a generalized Halton sequence.

21. A computer graphics system as defined in claim 19 or claim 21 in which the selected function is $L(x,y)$, representing the colour at point (x,y) in the image.

22. A computer graphics method for generating a pixel value for a pixel in an image, the pixel being representative of a point in a scene, the pixel value generated so as to provide a jittering that is represented by an evaluation of an integral of a

-36-

selected function over an area in the image for the pixel, the computer graphics method comprising the steps of:

- A. generating a set of sample points representing points in a plurality of contiguous pixels in the image, the plurality of contiguous pixels including the pixel for which the pixel value is to be generated, the sample points being generated using a predetermined strictly-deterministic low-discrepancy sequence,
- B. generating a plurality of function values each representing an evaluation of said selected function at one of the sample points;
- C. generating the pixel value for the pixel as the average of said function values.

23. A computer graphics method as defined in claim 22 in which said predetermined low-discrepancy sequence is a generalized Halton sequence.

24. A computer graphics method as defined in claim 22 or claim 23 in which the selected function is $L(x,y)$, representing the colour at point (x,y) in the image.

25. A computer graphic system for generating a pixel value for a pixel in an image; the pixel being representative of a point in a scene using strictly-deterministic low-discrepancy sequence, such as Halton sequences, as sample points for evaluating intervals which are used to simulate a number of computer graphics techniques.

26. The system of claim 25, wherein the system comprises the system of any one of claims 1, 2, 3, 7, 8, 9, 13, 14, 15, 19, 20 or 21.

27. A computer graphics method for generating a pixel value for a pixel in an image; the pixel being representative of a point in a scene using strictly-deterministic low-discrepancy sequence, such as Halton sequences, as sample points for evaluating

-37-

intervals which are used to simulate a number of computer graphics techniques.

28. The system of claim 27, wherein the method comprises the method of any one of claims 4, 5, 6, 10, 11, 12, 16, 17, 18, 22, 23 or 24.

29. Use of strictly-deterministic low-discrepancy sequences, such as Halton sequences, in a computer graphics system for generating a pixel vale for a pixel in an image.

30. Use according to claim 29 wherein the system is selected from the systems of claims 25 or 26.

31. Use of strictly-deterministic low-discrepancy sequences, such as Halton sequences, in a computer graphics method for generating a pixel vale for a pixel in an image.

32. Use according to claim 31 wherein the method is selected from the method of claims 27 or 28.

33. A computer system as hereinbefore described with reference to, and/or as illustrated by, the accompanying drawings.

34. A computer method as hereinbefore described with reference to, and.or as illustrated by, the accompanying drawings.

FIG. 1

2/6

FIG. 2

100. COMPUTER GRAPHICS SYSTEM 10 IDENTIFIES POINT IN SCENE FOR WHICH PIXEL VALUE IS TO BE GENERATED.

101. COMPUTER GRAPHICS SYSTEM 10 GENERATES "N" ELEMENTS OF A TWO-DIMENSIONAL HALTON SEQUENCE REPRESENTING POINTS ON THE LIGHT SOURCE WHICH ARE TO BE USED IN APPROXIMATION OF THE PIXEL VALUE TO PROVIDE FOR APPEARANCE OF SOFT SHADOWS IN IMAGE INCLUDING PIXEL WHOSE PIXEL VALUE IS BEING GENERATED.

102. FOR EACH OF THE "N" ELEMENTS OF THE TWO-DIMENSIONAL HALTON SEQUENCE GENERATED IN STEP 101, COMPUTER GRAPHICS SYSTEM 10 GENERATES A VALUE FOR THE SOFT SHADOWS ILLUMINATION FUNCTION (EQUATION (7)), USING THE ELEMENT OF THE HALTON SEQUENCE AS THE COORDINATES OF THE POINT ON THE LIGHT SOURCE.

103. COMPUTER GRAPHICS SYSTEM 10 GENERATES PIXEL VALUE FOR POINT IN SCENE AS AVERAGE OF THE VALUES GENERATED IN STEP 102.

3/6

FIG. 3

110. COMPUTER GRAPHICS SYSTEM 10 IDENTIFIES POINT IN SCENE FOR WHICH PIXEL VALUE IS TO BE GENERATED.

111. COMPUTER GRAPHICS SYSTEM 10 GENERATES "N" ELEMENTS OF A TWO-DIMENSIONAL HALTON SEQUENCE REPRESENTING POINTS (X',Y') ON LENS WHICH ARE TO BE USED IN APPROXIMATION OF THE PIXEL VALUE TO PROVIDE SIMULATION OF DEPTH OF FIELD FOR THE LENS IN IMAGE INCLUDING PIXEL WHOSE PIXEL VALUE IS BEING GENERATED.

112. FOR EACH OF THE "N" ELEMENTS OF THE TWO-DIMENSIONAL HALTON SEQUENCE GENERATED IN STEP 111, COMPUTER GRAPHICS SYSTEM 10 GENERATES A VALUE FOR THE LUMINANCE FUNCTION $L\text{-}(\text{BAR}) (X,Y,X',Y')$, USING THE ELEMENT OF THE HALTON SEQUENCE AS THE COORDINATES OF THE POINT ON THE LENS (X',Y') .

113. COMPUTER GRAPHICS SYSTEM 10 GENERATES A PIXEL VALUE FOR POINT IN SCENE AS THE AVERAGE OF THE VALUES GENERATED IN STEP 112.

4/6

FIG. 4

120. COMPUTER GRAPHICS SYSTEM 10 IDENTIFIES POINT IN SCENE FOR WHICH PIXEL VALUE IS TO BE GENERATED.

121. COMPUTER GRAPHICS SYSTEM 10 GENERATES "N" ELEMENTS OF A ONE-DIMENSIONAL HALTON SEQUENCE REPRESENTING POINTS IN TIME "T" WHICH ARE TO BE USED IN APPROXIMATION OF THE PIXEL VALUE TO PROVIDE SIMULATION OF MOTION BLUR IN IMAGE INCLUDING PIXEL WHOSE PIXEL VALUE IS BEING GENERATED.

122. FOR EACH OF THE "N" ELEMENTS OF THE ONE-DIMENSIONAL HALTON SEQUENCE GENERATED IN STEP 121, COMPUTER GRAPHICS SYSTEM 10 GENERATES A VALUE FOR THE LUMINANCE FUNCTION $L(X,Y,T)$, USING THE ELEMENT OF THE HALTON SEQUENCE AS THE POINT IN TIME "T" OVER WHICH MOTION BLUR IS TO BE GENERATED.

123. COMPUTER GRAPHICS SYSTEM 10 GENERATES A PIXEL VALUE FOR POINT IN SCENE AS THE AVERAGE OF THE VALUES GENERATED IN STEP 122.

5/6

FIG. 5

130. COMPUTER GRAPHICS SYSTEM 10 IDENTIFIES IMAGE REGION FOR WHICH PIXEL VALUES ARE TO BE GENERATED

131. COMPUTER GRAPHICS SYSTEM 10 GENERATES "N" ELEMENTS OF A TWO-DIMENSIONAL HALTON SEQUENCE REPRESENTING POINTS "(X,Y)" ON IMAGE REGION FOR WHICH PIXEL VALUES ARE TO BE GENERATED, WHICH POINTS ARE TO BE USED IN APPROXIMATION OF PIXEL VALUES TO PROVIDE SIMULATION OF JITTERING FOR THE PIXELS IN THE IMAGE REGION IDENTIFIED IN STEP 130.

132. FOR EACH OF THE PIXELS CONTAINED IN THE IMAGE REGION, IDENTIFY THE POINTS "(X,Y)" IDENTIFIED BY THE TWO-DIMENSIONAL HALTON SEQUENCE GENERATED IN STEP 131 THAT ARE CONTAINED WITHIN THE AREA OF THE PIXEL.

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
Y	MOROKOFF AND CARFLISCH: "QUASI-MONTE CARLO INTEGRATION" JOURNAL OF COMPUTATIONAL PHYSICS, vol. 122, no. 2, December 1995, USA, pages 218-230, XP002041721 see page 219, left-hand column, line 2 - right-hand column, line 17 see page 230, left-hand column, line 17 - line 26 --- -/--	1-34

☒ Further documents are listed in the continuation of box C.

☐ Patent family members are listed in annex.

* Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"A" document member of the same patent family

Date of the actual completion of the international search

25 September 1997

Date of mailing of the international search report

15.10.97

Name and mailing address of the ISA

European Patent Office, P.B. 5818 Patentlaan 2
